Introduction
Cyclooctatin is a potent inhibitor of lysophospholipase, which catalyzes the hydrolysis of the fatty acid ester bonds of lysophospholipids. This inhibitor was isolated from the broth of *Streptomyces melanosporoferaciens* MI614-43F2 while screening for lead compounds for the development of anti-inflammatory drugs targeting lysophospholipase.

Cyclooctatin has a unique tricyclic diterpene skeleton characterized by a 5-8-5 fused ring system (Fig. 1A). In the biosynthesis of cyclooctatin, the biosynthetic gene product CotB1 synthesizes geranylgeranyl diphosphate (GGDP) from isopentenyl diphosphate and dimethylallyl diphosphate, and then CotB2 catalyzes the stereospecific cyclization of GGDP to give cycloocta-9-en-7-ol (Fig. 1B). Next, the cytochrome P450, CotB3, likely catalyzes the stereospecific hydroxylation of cycloocta-9-en-7-ol at C-5 to form cycloocta-9-en-5,7-diol. Finally, the other cytochrome P450, CotB4, catalyzes the hydroxylation of cycloocta-9-en-5,7-diol at C-18 to yield the final product, cyclooctatin. Although cyclization is a key reaction in cyclooctatin biosynthesis, mechanism of formation of stereo- and regio specific ring is unclear since no 3D-structural information has been available to date. To clarify the cyclization mechanism of CotB2 and to design the cyclase with broad product diversity, we newly determined the crystal structure of high resolution apo-form of CotB, and the complex with a substrate analog, geranylgeranylthiodiphosphate (GGSPP).

Materials and Methods

Crystallization - Crystal of apo CotB2 (apo type II) was obtained by the hanging-drop vapor-diffusion method. The reservoir solution contained 0.1 M HEPES-NaOH (pH 7.0-8.5) and 2.2 M ammonium formate. Crystal of CotB2 complexed with GGSSP/Mg$^{2+}$ (GGSSP/Mg$^{2+}$ type I) is obtained with reservoir solution which contains 20% PEG6000, 100 mM Bicine-NaOH (pH 9.0), 5 mM MgSO$_4$, and 1 mM GGSSP.

Data collection and processing – The X-ray diffraction data were collected using the beamline NW-12, 5A at PF. The image sets were integrated and scaled using HKL2000.

Results and Discussion
Active site closure induced by GGSSP binding - The crystal structure of apo form of CotB2 was determined at 1.8 Å resolution by means of MR method with the model of apo form with 2.4 Å resolution as a search model. Apo CotB2 is composed of a terpene cyclase fold (Gly9-Asn292), forming 13 α-helices. The electron density of N-terminal and C-terminal residues of CotB2 (Met1-Ala8 and Lys293-Gln307) was not observed, indicating that this region is disordered in the crystal. In apo form, DDMD motif and NSE/DTE motif conserved among terpene cyclase family are located at the putative active site. In the GGSSP/Mg$^{2+}$ form, GGSSP is bound at the pocket of the enzyme with a unique S-shaped conformation (Fig. 2B). Mg$^{2+}$ ion was also bound near the diphosphate group of GGSSP. Asn220, Ser224, and Glu228 from NSE/DTE motif binds with Mg$^{2+}$. The diphosphate group of GGSSP was recognized by Arg117 and bound with Mg$^{2+}$. Asp111 from DDMD motif forms a hydrogen bond with Arg294 from basic motif to close the active site. Newly defined Tyr295 forms diphosphate group of GGSSP. C20 carbon chain was surrounded by many aromatic and hydrophobic residues and several Asn residues.
